Introduction

The Madden-Julian Oscillation is the dominant component of intraseasonal variability in the tropical atmosphere.

Its structure is potentially influenced by multiscale processes and extratropical motions.

A partitioning technique is proposed that can separate the wind field within the tropics into an irrotational component ($U_\phi$), a non-divergent component ($U_\psi$), and a third component associated with the extratropics ($U_\chi$).

We analyze the contribution of these components to the MJO.

Free Space Green’s Functions

A vorticity element, $C_\psi$, centered at $(\lambda_c, \varphi_c, \omega_c)$ contributes to the wind at any point $(\lambda, \varphi)$. One reconstructs the total non-divergent wind field induced at $(\lambda, \varphi)$ using the following equation:

$$u(\lambda, \varphi) = \frac{1}{4\pi} \sum_{\varphi'=-\pi}^{\pi} C_\psi \frac{\sin \varphi - \sin \varphi'}{\cos \varphi' \cos (\lambda - \lambda')}$$

$$v(\lambda, \varphi) = \frac{1}{4\pi} \sum_{\varphi'=-\pi}^{\pi} C_\psi \frac{\cos \varphi - \cos \varphi'}{\sin \varphi' \cos (\lambda - \lambda')}$$

Where $(\lambda, \varphi)$ represent longitude and latitude, and $\omega$ represents the central angle between two points on the sphere.

Coherence – Background Flow

- The spectral regions of highest coherence do not correspond to any equatorial wave mode.
- Fluctuations are nearly out of phase.
- Appearance looks similar to extratropical Rossby waves.

Fig. 2: Coherence (left) and phase (right) of $U_\psi$ from 15°S-15°N with geopotential height anomalies from 30°-45° (N and S).

Composites

Fig. 4: Left: Background flow for MJO phases 1-4. Contours denote geopotential height anomalies (red-positive, green-negative). Right: Same as Fig. 3 but the geopotential height anomalies are averaged from 35°-45° N and S.

Fig. 5: Phase-latitude diagram of $U_\phi$ and $U_\psi$ at 850 hPa averaged over NDFM. Red contours denote positive height anomalies and green contours denoting negative anomalies. The zero height anomaly is marked as a black line. Contour interval is 2 m.

Conclusions

- The local components ($U_\phi$ and $U_\psi$) show a classical MJO pattern, with wind reversal with height.
- $U_\phi$ is weaker, but of larger horizontal scale, than the other wind components.
- The background flow shows an oscillation in the central Pacific associated with extratropical height anomalies. The anomaly has an equivalent barotropic structure.
- An oscillation in the zonally averaged background flow is seen, associated with the zonally averaged extratropical height anomalies.
- The phase locking and sign of the background winds with respect to the local convective envelope of the MJO suggest that they might have some importance in determining the structure and propagation of the MJO.
- Future work includes further studies of how some aspects of the background flow can potentially modulate the strength and structure of the MJO, and its initiation.
